Keywords: frequent closed itemsets, Galois connection, granular computing, association rules, data mining

Received: February 6, 2014

To avoid generating an undesirably large set of frequent itemsets for discovering all high confidence association rules, the problem of finding frequent closed itemsets in a formal mining context is proposed. In this paper, aiming to these shortcomings of typical algorithms for mining frequent closed itemsets, such as the algorithm A-close and CLOSET, we propose an efficient algorithm for mining frequent closed itemsets, which is based on Galois connection and granular computing. Firstly, we present the smallest frequent closed itemsets and its characters, contain some properties and theorems, then propose a novel notion, called the smallest frequent closed granule, which can help the algorithm save reading the database to reduce the costed I/O for discovering frequent closed itemsets. And then we propose a novel model for mining frequent closed itemsets based on the smallest frequent closed granules, and a connection function for generating the smallest frequent closed itemsets. The generator function create the power set of the smallest frequent closed itemsets in the enlarged frequent 1-item manner, which can efficiently avoid generating an undesirably large set of candidate smallest frequent closed itemsets to reduce the costed CPU and the occupied main memory for generating the smallest frequent closed granules. Finally, we describe the algorithm for the proposed model. On these different datasets, we report the performances of the algorithm and its trend of the performances to discover frequent closed itemsets, and further discuss how to solve the bottleneck of the algorithm. For mining frequent closed itemsets, all these experimental results indicate that the performances of the algorithm are better than the traditional and typical algorithms, and it also has a good scalability. It is suitable for mining dynamic transactions datasets.

Povzetek: Opisan je nov algoritem asociativnega učenja za pogoste entitete.

1 Introduction

Association rules mining is introduced in [1], Agrawal et al. firstly propose a classic algorithm for discovering association rules in [2], namely, the Apriori algorithm. However, it is also well known that mining frequent patterns often generates a very large number of frequent itemsets and association rules, which reduces not only efficiency but also effectiveness of mining since users have to sift through a large number of mined rules to discover useful ones. In order to avoid the shortcoming, Pasquier et al. introduce the problems of mining frequent $(i+1)$ – generators are created by joining i – generators. closed itemsets in [3], and propose an efficient Apriori-
heard mining algorithm, called A algorithm Subsequent. For the first method, the advantages are the less usage of based mining algorithm, called A-close. Subsequent, Zaki and Hsiao propose another mining algorithm in [4], called CHARM, which improves mining efficiency by exploring an item-based data structure. However, we find A-close and CHARM are still costly when mining long patterns or low minimum support thresholds in large database, especially, CHARM depends on the given data structure and need the overlarge memory. As a continued study on frequent patterns mining without candidate generation in [5], J. Pei et al. propose an efficient method for mining frequent closed itemsets without candidate

generation in [6], called CLOSET. There are more study works for mining frequent closed itemsets in [7-13]. The familiar algorithms include MAFIA in [7], CLOSE+ in [8] and DCI-CLOSED in [9].

At present, for mining frequent closed itemsets, there are two types of main current methods as follows:

The first is the method of mining frequent closed itemsets with candidate based on the Apriori algorithm in [3 and 14]. The A-close algorithm in [3] is a well-known typical algorithm for the first method, which adopts the bottom-up search strategy as the Apriori-like in [2], and constructs the set of generators in a level-wise manner: couped man memory for generating the smallest
corithm for the proposed model. On these different
time and its trend of the performances to discover
solve the bottleneck of the algorithm. For mining
and it also has a good s memory, simple data structure, and easy implementing it and maintaining; its disadvantages are the more occupied CPU for matching candidate patterns, and the overlarge costed I/O for the repeatedly scanning the database to compute the support.

The second is the method of mining frequent closed itemsets without candidate based on the FP-tree structure in [6, 15 and 16]. The CLOSET algorithm in [6] is an extended study of the FP-Growth for mining frequent patterns in [5]. For the second method, the advantages

are reducing the overlarge computing corresponding to 2 the joined potential generators in the A-close algorithm, and saving the costed I/O of reading the database. But it has these disadvantages, such as complex data structure costs more memory, creating recursion FP-tree occupies more CPU, and implementing it is troublesome.

Rough set theory in [17] and formal concept analysis in [18 and 19] are two efficient methods for the A, R , where representation and discovery of knowledge in [20 and $U = \{u_1, u_2, ..., u_n\}$ ($n = U$), called the universe of 21]. Rough set theory and formal concept analysis are discourse, is a finite nonempty set of objects; actually related and often complementary approaches to
data analysis but rough set models enable us to precisely
 $A = \{a_1, a_2, ..., a_m\}$ $(m = A)$, called the attributes data analysis, but rough set models enable us to precisely define and analyse many notions of granular computing set, is also a finite nonempty set of attributes;
in [22 and 23]. $R \subseteq U \times A$, called the relations, is a binary relation in [22 and 23].

Reference [22] develops a general framework for the study of granular computing and knowledge reduction in $(u,a) \in R$ denotes the fact that the object $u (u \in U)$ is formal concept analysis. In formal concept analysis, related to the attribute $a (a \in A)$. granulation of the universe of discourse, description of granules, relationship between granules, and computing
with granules are issues that need further scrutiny. Since
concise, and then let the attribute $a(a \in A)$ be Boolean, with granules are issues that need further scrutiny. Since the basic structure of a concept lattice induced from a where each attribute is regarded as an item, i.e. the formal context is the set of object concepts and every formal concept in the concept lattice can be represented as a join of some object concepts, each object concept can be viewed as an information granule in the concept lattice.

thus a formal concept, which is a pair consisting of a set of objects (the extension) and a set of attributes (the intension) such that the intension consists of exactly maximal set of items shared by all objects $o (o \in O)$; those attributes that the objects in the extension have in $\{(I): P(A) \to P(U)$, namely common, and the extension contains exactly those objects that share all attributes in the intension in [22]. For the study of granular computing, the formal concept maximal set of objects that have all items i ($i \in I$); is defined as a granule, such as an information granule.

abstraction in [25], the ideas of granular computing have been widely investigated in artificial intelligence in [26], and the power set of A (i.e. $P(A)$). such as, granular computing has been applied to **Property 2.1** For a formal context $D = (U, A, R)$, if association rules mining in [27 and 28], where a partition
model of grapular computing is applied to constructing $Q, Q_1, Q_2 \subseteq U$ and $I, I_1, I_2 \subseteq A$, then we have: model of granular computing is applied to constructing information granule in [26], which depends on rough set theory in [29] and quotient space theory in [30].

In this paper, we propose a novel model based on $(1^*) O_1 \subseteq O_2 \Rightarrow \tilde{S}(O_1) \supseteq \tilde{S}(O_2)$;

In this paper, we propose a novel model based on $(2) I \subset \tilde{S}(O) \Leftrightarrow O \subset \{ (I) \}.$ granular computing, namely, an efficient algorithm for of generators in the enlarged frequent1 *item* manner to reduce the costed I/O.

The rest of the paper is organized as follows:

closed itemset and granular computing; In Section 3, we propose a novel model for mining frequent closed $I_1, I_2 \subseteq A$, then we have: itemsets based on granular computing; In Section 4, we Extension: (3) $I \subseteq h(I)$; describe the efficient mining algorithm; Section 5 reports the performance comparison of our with A-close and Idempotency: $(4) h(h(I)) = h(I)$; CLOSET. In Section 6, we summarize study work and discuss some future research directions.

4 The efficient mining algorithm

In this section, we use an efficient mining algorithm to describe the novel model, which is denoted by EMFCI.

4.1 Generator function

Here, we propose a function for generating the intension of the smallest frequent closed granules.

Definition 4.1 Set vector operation \Box for two sets is defined as follows:

Let $P = \{p_1, p_2, ..., p_m\}, Q = \{q_1, q_2, ..., q_n\}$ be two sets,

set, the formal granule *G I I* , () is said to be the { , () | } *FG G I I I FC min min* 1 2 1 2 { } { } 0 { } { } ... { } ... { } *n m^p p q q q p* 1 1 1 1 2 1 2 2 1 2 2 2 1 2 { } { , } { , } ... { , } { } { , } { , } ... { , } { } { , } { , } ... { , } *n n m m m m n p p q p q p q p p q p q p q p p q p q p q* 1 1 1 1 2 1 2 2 1 {{ },{ , },{ , },...,{ , },{ },{ , }, *ⁿ p p q p q p q p p q* 2 2 2 1 2 { , },...,{ , },...,{ },{ , },{ , }, *n m m m p q p q p p q p q* ...,{ , } *m n p q* (Formal notation) 1 1 1 1 2 1 2 2 1 2 2 {{ },{ },{ },...,{ },{ },{ },{ }, *ⁿ p p q p q p q p p q p q* 2 1 2 ...,{ },...,{ },{ },{ },...,{ } *n m m m m n p q p p q p q p q* . (Simple notation) let *P Q*, be two sets, it is expressed as (,) *T f P Q P Q* . The application of *f P Q* (,) refers to Section 4.2. For example, for a formal context *D U A R* (, ,) , let *A* be a general itemset{ , , } *a b c* , and then we use the set vector operation to generate *P A p P A p* () (() 0) as (1) *P A*() 0 ; (2) { } () () (()) *T x x I a P A P A I P A* { } 0 {{ }} *a a* ;

The operation is the main idea of generator function,

follows:

(1)
$$
P(A) = 0
$$
 ;
\n(2) $I_x = \{a\} \Rightarrow P(A) = P(A) \cup (I_x^T \Box P(A))$

4.3 Example and analysis

Here, we firstly provide an example for the algorithm, and then analyse the pruning strategies in the algorithm.

5 Performance and scalability study

Finally, for the bottleneck of the algorithm EMFCI, we improve it to get the algorithm IEMFCI, and report its performances on the extended high dimension dataset to
show the scalebility of the electric EMECI show the scalability of the algorithm EMFCI.

There are two original datasets as follows:

The first is the Food Mart 2000 retail dataset, which comes from SQL Server 2000. It contains 164558 records in 1998. By the same customer at the same time as a basket, we take items purchased from these records. Because the supports of the bottom items are small, we generalize the bottom items to **the product department**. Finally, we obtain 34015 transactions with time-stamps. It is a dataset with the **Boolean** attributes. **Example 10** Exertion and the performances of the algorithm

Table 2: The datasets used in the experiments.

5.1 The experiments of performance comparison

In this section, for discovering frequent closed itemsets on these different datasets, we compare the algorithm EMFCI with the algorithm A-close and CLOSET from the following two aspects, namely, one is comparing the performances among them as the minimal support is added; the other is comparing them as the number of frequent closed itemsets is added.

1. Testing on the original datasets

For the two original datasets, we firstly compare the algorithm EMFCI with the A-close and CLOSET based on the varying minimal support and the number of frequent closed itemsets. These experimental results are described as figure 1, 2, 3, and 4, respectively.

Figure 1: Performance comparison with the support on dataset 1.

Figure 2: Performance comparison with the number of frequent closed itemsets on dataset 1.

Figure 3: Performance comparison with the support on dataset 4.

Figure 4: Performance comparison with the number of frequent closed itemsets on dataset 4.

Based on the comparison results from figure 1, 2, 3, Based on the comparison results from figure 1, 2, 3, $\int_{\frac{4}{3}}^{\frac{4}{3}} x$, and 4, we know that the performances of the algorithm EMFCI are better than the A-close and CLOSET.

Obviously, the algorithm CLOSET is also superior to the A-close. Hence, we don't compare the EMFCI with the A-close in the following experiments.

2. Testing on the extended datasets

We further report the performances of the algorithm EMFCI on the extended datasets. Based on the different minimal support and the number of frequent closed
itemsets, we compare the EMFCI with the CLOSET, the
experimental results are described as figure 5 to 12. itemsets, we compare the EMFCI with the CLOSET, the experimental results are described as figure 5 to 12.

Figure 5: Performance comparison with the support on dataset 2.

Figure 6: Performance comparison with the number of frequent closed itemsets on dataset 2.

Figure 7: Performance comparison with the support on dataset 3.

Figure 8: Performance comparison with the number of frequent closed itemsets on dataset 3.

Figure 9: Performance comparison with the support on dataset 5.

Figure 10: Performance comparison with the number of frequent closed itemsets on dataset 5.

Figure 11: Performance comparison with the support on dataset 6.

Figure 12: Performance comparison with the number of frequent closed itemsets on dataset 6.

Based on the comparison results from figure 5 to 12, we know that the performances of the algorithm EMFCI are also better than the CLOSET on the datasets with the Boolean or quantitative attributes.

5.2 The relationships between these parameters and performances

In this part, we mainly discuss the relationships between the performances and the following parameters:

transactions in the mining database.

Informatica 39 (2015) 87–98
 $\Box P(I)$ I, is the number of nonempty power sets for

oute values, called the **search space** of the algorithm,
 $P(I)$ is the smallest frequent closed itemsets from the

oute set A, $P(I)$ is def attribute values, called the **search space** of the algorithm, attribute values, called the **search space** of the algorithm,
where *I* is the smallest frequent closed itemsets from the
attribute set *A*, $P(I)$ is defined as the power set of *I*. **94** Informatica **39** (2015) 87–98
 $\Box P(I)$ I, is the number of nonempty power sets for

attribute values, called the **search space** of the algorithm,

where *I* is the smallest frequent closed itemsets from the

attribut Informatica 39 (2015) 87–98
 $\Box P(I)$ [, is the number of nonempty power sets for

vute values, called the **search space** of the algorithm,
 $\frac{3}{8}$ $\frac{1}{8}$ α
 $\frac{1}{8}$ α

zute set *A*, $P(I)$ is defined as the p **p** *p* to the number of nonempty power sets for the values, called the **search space** of the algorithm,
 p to $\frac{1}{2}$ ($\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2}$ $\frac{1}{2$

Here, the representation of the performances has two kinds of parameters as follows:

input to output for mining frequent closed itemsets.

p , is defined as the improved ratio of the runtime between the algorithm EMFCI and CLOSET, which is denoted by the following equation:

and the search space

(1)Reporting the relationships on the extended dataset of the first original dataset

For the first original dataset, namely, dataset 1, we test the trend of the performances as the search space is increasing on dataset 2, which is the extended dataset with replicating three attributes of the first dataset. As the search space is varying, the trend of the runtime for the algorithm EMFCI is expressed as figure 13, the trend of the improved ratio between the algorithm EMFCI and CLOSET is expressed as figure 14.

Figure 13: The trend of the runtime on dataset 2.

Figure 14: The trend of the improved ratio on dataset 2.

Based on figure 13, we know that the runtime is added as the search space is increasing. Based on figure 14, we find that the improved ratio is reduced as the search space is increasing.

(2)Reporting the relationships on the extended dataset of the second original dataset

For the second original dataset, namely, dataset 4, we extend an attribute to get dataset 5, and test the trend of the performances on the dataset. The experimental results are expressed as figure 15 and 16, respectively.

Figure 15: The trend of the runtime on dataset 5.

Figure 16: The trend of the improved ratio on dataset 5.

According to figure 15 and 16, we get the similar comparisons results as above. Hence, we can draw the following conclusions:

The runtime of the algorithm EMFCI is added as the search space is increasing; on the contrary, the improved ratio is reduced. Namely, if the search space is increasing, the performances of the algorithm EMFCI will become worse and worse. In other word, the algorithm is not suitable for mining the dataset with too many smallest frequent closed itemsets.

2. The relationships among the performances, the search space and the number of objects

(1)Reporting the relationships on the first original dataset and its extended dataset

For the first original dataset (dataset 1), and its extended dataset, dataset 3 with replicating its objects four times, we test the trend of the performances as the search space is increasing on the two datasets. As the search space is varying, the trend of the runtime for the algorithm EMFCI is expressed as figure 17, the trend of the improved ratio between the algorithm EMFCI and CLOSET is expressed as figure 18.

Figure 17: The trend of the runtime on dataset 1 and 3.

Figure 18: The trend of the improved ratio on dataset 1 and 3.

Based on figure17, we know that the runtime of the algorithm is added as the search space or the number of objects is increasing.

Based on figure18, we find that the improved ratio of the algorithm is reduced as the search space is increasing, but it become relatively stable as the number of objects is increasing.

(2)Reporting the relationships on the second original dataset and its extended dataset

For the second original dataset, namely, dataset 4, we replicate its objects one time to get dataset 6, and test the trend of the performances on the dataset 4 and 6. The

experimental results are expressed as figure 19 and 20, respectively.

Figure 19: The trend of the runtime on dataset 4 and 6

Figure 20: The trend of the improved ratio on dataset 4 and 6

According to figure 19 and 20, we draw the same conclusions as follows:

The runtime of the algorithm EMFCI is added as the search space or the number of objects is increasing, the
improved ratio of the algorithm is reduced as the search In this paper, we let $||P(I_m)|| < \} = 2^{19}$. If $\}$ is too big, improved ratio of the algorithm is reduced as the search space is increasing, but it become relatively stable as the number of objects is adding. Namely, the performances of the algorithm EMFCI will become relatively stable as the number of objects is increasing. Hence, it is suitable for mining dynamic transactions datasets.

According to all these experimental results, we can **draw the following conclusions**:

(1) The performances of the algorithm EMFCI are better than the traditional typical algorithms for mining frequent closed itemsets on the datasets with the Boolean attributes or the 1uantitative attributes.

(2) The runtime of the algorithm EMFCI is added as the search space. If the search space is too large, its performances will become worse and worse. This is the following experiments)
bottleneck of the algorithm. Step1. $FG = \{ \langle a \rangle, \{1,3,5\} \rangle, \langle b \rangle, \{2,3,4\} \rangle$, bottleneck of the algorithm.

(3) The runtime of the EMFCI is also added as the number of objects is increasing.

(4) For the algorithm CLOSET, the improved ratio

(4) For the algorithm CLOSET, the improved ratio

Step3. **Partitioning** the search space, get two search

Step3. **Partitioning** the search space, get two search of the algorithm is reduced as the search space is adding,
but it become relatively stable as the number of objects is $\sum_{i=1}^{N} \{a_i\} \{b_i\}, F_{i} = \{\{c\}, \{e\}\}\$, where $||P(F_i)|| \leq 4$. but it become relatively stable as the number of objects is increasing. Namely, the performances of the EMFCI will become relatively stable as the number of objects is increasing. It is suitable for mining dynamic transactions datasets. For the contentional value of the search space in \overline{P} (\overline{P}). **Example** in section 4.3, we use the algorithm tetrational viptical algorithms for mains \overline{P} . The contempt lin section 4.3, we use the algorithm frequent closed itemsets on the datasets with the Boolean

attributes or the Juantitative attributes.

(2) The runtime of the algorithm EMFCI is added as

the search space. If the search space is too large, its

performan attronauces or the translation entrodes.

(2) The runtime of the algorithm EMFCI is added as of which is descreased will become worse and worse. This is the following experiment

bottleneck of the algorithm.

(3) The runt

5.3 A further discussion for solving the bottleneck of the algorithm

Based on these conclusions in section 5.2, for the formal performance of EMFCI will become worse and worse.

In this section, we adopt **a partitioning method** to avoid the bottleneck. In other word, the overlarge search space is divided into some smaller search spaces. The theoretical basis can be described as follows:

following $\|P(I)\| = \prod_{i=1}^m (\|V_{a^{i_1}}\|+1) - 1$, namely,

\n Information of the

\n In this section, we adopt a **partitioning method** to avoid the bottleneck. In other word, the overlapping search space is divided into some smaller search spaces. The theoretical basis can be described as follows:\n Let $I = \{a^{i_1}, a^{i_2}, \ldots, a^{i_m}\} (I \subseteq A)$, and then we have the following $||P(I)|| = \prod_{i=1}^m (||V_{a^{i_i}}|| + 1) - 1$, namely,\n $||P(I)|| + 1 = \prod_{i=1}^m (||V_{a^{i_i}}|| + 1) - \cdots (||V_{a^{i_m}}|| + 1) \cdots (||P(I_{m_1})|| + 1) - \cdots (||P(I_{m_1})|| + 1) - \cdots (||P(I_{m_1})|| + 1) + \cdots (||P(I_{m_n})|| +$

Where
$$
I_{m_1} = \{a^{t_1}, a^{t_2}, ..., a^{t_m} \},
$$

\n $I_{m_2} = \{a^{t_{m_1+1}}, a^{t_{m_1+2}}, ..., a^{t_{m_1+m_2}} \}, ...,$
\n $I_{m_k} = \{a^{t_{m_1+m_2+...+m_{(k-1)}+1}}, ..., a^{t_{m_1+m_2+...+m_{(k-1)}+m_k}} \}.$

the method also has the same bottleneck; if $}$ is too small, the cost of partitioning search space is expensive. For these two cases, their performances are expressed as figure 23. (|| $P(I_{m_1}) || +1 \rangle \cdot (|| P(I_{m_2}) || +1) \cdot ... \cdot (|| P(I_{m_l}) || +1);$

Where $I_{m_1} = \{a^{t_1}, a^{t_2}, ..., a^{t_{m_1}}\}, \dots$
 $I_{m_2} = \{a^{t_{m_1+1}}, a^{t_{m_1+2}}, ..., a^{t_{m_1+m_2}}\}, \dots,$
 $I_{m_k} = \{a^{t_{m_1+m_2+m_3+m_4+m_5+m_5+m_6+m_7+m_8}}\}$.

In this paper, we let $|| P(I_{m$ Where $I_{m_1} = \{a^{t_1}, a^{t_2}, ..., a^{t_{m_1m_2}}\} \ldots$
 $I_{m_k} = \{a^{t_{m_1m_2}...n_{k-1},1}, ..., a^{t_{m_1m_2}...n_{k-1},m_k} \}$.

In this paper, we let $\|P(I_{m_k})\| \leq \} = 2^{19}$. If $\}$ is too big, method also has the same bottleneck; if $\}$ is

The partitioning method is used in the algorithm EMFCI, which is called improved EMFCI, i.e. IEMFCI.

5.3.1 Example

For the example in section 4.3, we use the algorithm IEMFCI to discover frequent closed itemsets, the course of which is described as follows, where $} = 4$.

(**Note:** $\xi = 4$ used in the example, $\xi = 2^{19}$ used in the following experiments)

$$
\langle \{c\}, \{1, 2, 5\} \rangle, \langle \{e\}, \{3, 4, 5\} \rangle
$$

ep2.
$$
F = \{ \{a\}, \{b\}, \{c\}, \{e\} \}, || P(F) ||= 15 > 3 = 4
$$
.

$$
I_{m_k} = \{a^{(r_{\text{unary-in}}_{k-1})+1}, \ldots, a^{(r_{\text{unary-in}}_{k-1})+m_k} \}.
$$

In this paper, we let $|P(I_{m_k})|| \leq 2^{-19}$. If $\}$ is too big,
the method also has the same bottleneck; if $\}$ is too
small, the cost of partitioning search space is expensive.
For these two cases, their performances are expressed as
figure 23.
The partitioning method is used in the algorithm
EMFCI, which is called improved EMFCI, i.e. IEMFCI.
5.3.1 Example
For the example in section 4.3, we use the algorithm
IEMFCI to discover frequent closed itemsets, the course
of which is described as follows, where $\}$ = 4.
(Note: $\}$ = 4 used in the example, $\}$ = 2^{19} used in the
following experiments)
Step1. $FG = \{, b, \{2,3,4\} >$,
 $<\{c\}, \{1,2,5\} >, e, \{3,4,5\} > \}$.
Step2. $F = \{\{a\}, \{b\}, \{c\}, \{e\}\}, || P(F) ||= 15 > \}$ = 4.
Step3. **Partitioning** the search space, get two search
spaces $F_1 = \{\{a\}, \{b\}\}, F_2 = \{\{c\}, \{e\}\}, where || P(F_i)|| \le 4$.
Step4. For the first search space $F_1 = \{\{a\}, \{b\}\}$, have
 $Q \Gamma = \{a\} \Rightarrow S_c = \{\{a\}\}$
 $FG_{min}^1 = \{\langle a\}, \{1,3,5\} > \}, FC_{min}^1 = \{\{a\}\}\}$;
 $Q \Gamma = \{b\} \Rightarrow S_c = \{\{b\}, \{ab\}\}$
 $FG_{min}^1 = \{\langle a\}, \{1,3,5\} > \}, FC_{min}^1 = \{\{a\}\}\}$, have
 $Q \Gamma = \{c\} \Rightarrow S_c = \{\{b\}\}$.
For the second search space $F_2 = \{\{c\}, \{e\}\}$, have
 $Q \Gamma = \{c\} \Rightarrow S_c = \{\{c\}\}$.

$$
\begin{aligned} \textcircled{1} \Gamma &= \{c\} \Rightarrow S_c = \{\{c\}\} \\ FG_{\text{min}}^2 &= \{\langle c\}, \{1, 2, 5\} > \}, \, FC_{\text{min}}^2 = \{\{c\}\} \, ; \end{aligned}
$$

$$
\begin{aligned} \textcircled{2} \Gamma &= \{e\} \Rightarrow S_c = \{\{e\}, \{ce\}\} \\ FG_{min}^2 &= \{< \{c\}, \{1, 2, 5\} > ,lt; \{e\}, \{3, 4, 5\} > \}, \\ FC_{min}^2 &= \{\{c\}, \{e\}\} \,. \end{aligned}
$$

96 Informatica 39 (2015) 87–98
 $\bigcirc \mathcal{F} = \{e\} \Rightarrow S_e = \{\{e\}, \{ce\}\}\$
 $FG_{min}^2 = \{\{c\}, \{1, 2, 5\} > , \{e\}, \{3, 4, 5\} > \},$
 $FC_{min}^2 = \{\{c\}, \{1, 2, 5\} > , \{e\}, \{3, 4, 5\} > \},$

Step5. $F = \{FC_{min}^1, FC_{min}^2\}$, repeating the step2,

whe operation must be ended; otherwise, the algorithm need to continue to partition the search space.

CLOSET	$O(C ^2)$	$O(\mid C \mid)$	tł
IEMECI	$O((L/k+1)$ $ C $	$O(C /k \cdot A)$	

5.3.3 Test on the high dimension datasets

In this section, to show the scalability of the algorithm EMFCI, firstly, we compare the improved algorithm IEMFCI with EMFCI, A-close and CLOSET on the high dimension dataset (dataset 7 as table 1), which is an extended dataset based on the first original dataset. The **6** comparison results are expressed as figure 21 and 22, **EXECUAL CONSTRANE CONSTRANE CONSTRANE CONSTRANE CONSTRANE (SEE ARE CONSTRANE AND ASSOCIATE CONSTRANE CONSTRANE** For $D = (U, A, R)$, let C be a set of frequent closed

Then, for the improved algorithm IEMFCI, we adopt different parameters } to test its trend of performance, where $\} = 2^5$, $\} = 2^{19}$ and $\} = 2^{22}$. The comparison result the improved algorithm IEMFCI when the parameter of

Figure 23: The trend of performance with the different parameter on dataset 7.

Based on these comparisons, we draw the following conclusions:

Firstly, the improved algorithm IEMFCI is better than the algorithms EMFCI, A-close and CLOSET.

Table 3: Comparisons of the time and space complexity. The bottleneck in the algorithms EMFCI, especially,
when the search space $\Box P(I)$ is overlarge, the advantage Secondly, the improved algorithm IEMFCI gets rid of the bottleneck in the algorithms EMFCI, especially, of IEMFCI is very distinct.

> Finally, for the improved algorithm IEMFCI, the parameter of partitioning the search space is not too big, but it is not too small.

6 Conclusion

In this paper, for the shortcomings of typical algorithms for mining frequent closed itemsets, we propose an efficient algorithm for mining frequent closed itemsets, which is based on Galois connection and granular computing. We present the notion of smallest frequent closed granule to reduce the costed I/O for discovering frequent closed itemsets. And we propose a connection function for generating the smallest frequent closed itemsets in the enlarged frequent 1-item manner to reduce the costed CPU and the occupied main memory. But the number of the smallest frequent closed itemsets is too many, the performances of the algorithm become worse and worse, so we further discuss how to solve the bottleneck, namely, propose its improved algorithm on high dimension dataset. The algorithm is also suitable for mining dynamic transaction datasets.
