

OCCURRENCE OF THE RED KITE *Milvus milvus* IN SLOVENIA

Pojavljanje rjavega škarnika *Milvus milvus* v Sloveniji

The Red Kite is a bird of prey that breeds almost exclusively in Europe (BIRDLIFE INTERNATIONAL 2004). Globally, as well as in Europe, it has the status of a near threatened species (BIRDLIFE INTERNATIONAL 2015). The population as a whole has been in decline for almost three generations (BIRDLIFE INTERNATIONAL 2004, 2015). Western and southern European populations are resident, but most birds in the northeast are migratory (BIRDLIFE INTERNATIONAL 2017).

Although the Red Kite was present in Slovenia in historical times, most authors agree that it is a rare species with only few observations and specimens in museum collections (SCHULZ 1890, SCHIAVUZZI 1883, REISER 1925). It was assumed to be a breeder (GEISTER 1995) and an extremely rare winter visitor (SOVINC 1994). In the early 1990s it was listed as a rare bird in the breeding and wintering periods by the National Rarities Committee (KOMISIJA ZA REDKOSTI 1993). Although it occurs more often during migration, it was listed as a rare visitor in overviews of birds on Ljubljansko barje (TOME *et al.* 2005), at Medvedce reservoir (BORDJAN & BOŽIČ 2009), at Lake Cerknica (BORDJAN 2012B), at Vrbje fishpond (GAMSER & NOVAK 2013), in Ljubljana and surrounding areas (TOME *et al.* 2013) and at Sečovlje salt pans (ŠKORNIK 2012). An increased number of sightings was reported only for the Medvedce reservoir (BORDJAN 2012A). Due to the low number of sightings at individual sites, the phenology of the species in Slovenia has so far been missing, nor has there ever been an overview of the species' occurrence.

Data for the present review were collected from the journal *Acrocephalus*, from the online database

Atlas ptic NOAGS (<http://atlas.ptice.si/atlas>), from online birding groups, online photo galleries and directly from observers.

Between 1977 and January 2017, 117 records of 121 individuals were made. 113 of the observations concerning single individuals. Two individuals were observed together only four times. Most observations concerned migratory birds and only few records individuals present for more than one day. In 2009 and 2010, at least one individual was present at the Vodovnik farmhouse near Topolšica from April till October and November, respectively (I. JELENKO *pers. comm.*). Despite being present during the entire breeding season, breeding was not confirmed. Longer stays were also recorded at Savska loka near Dolsko (TRONTELJ 2008), in the SE part of Ljubljansko barje (ŠERE 2015, ATLAS PTIC 2017) and at Lake Šoštanj (ČELIK 1993).

The number of annual records has been rising from 1980 onwards (Figure 1; $R_{\text{Spearman}}: 0.71; p < 0.001; df = 36$). In the 1980s, on average less than one Red Kite was observed per year, 1.1 in the 1990s and 3.0, between 2000 and 2009, while, after 2009, 9 Red Kites were observed each year. Red Kites were observed in all months of the year with the fewest observations during the summer months (Figure 2). With the exception of the individual near Topolšica, only two observations were made between 20 Jun and 30 Aug. Fewer observations were recorded during the winter as well. In December and January, altogether six birds were observed (Figure 2). The first migratory Red Kites were recorded at the beginning of February. The number of observations rose until the start of April and eventually dropped towards its end (Figure 2). There is a second peak in May. During the autumn migration, the first Red Kites were observed at the end of August. The number of observations rose through September peaking in the beginning of October (Figure 2). The last autumn observation was made at Ljubljansko barje on 12 Nov (TOME *et al.* 2005).

Red Kites were sighted over much of the country, from Goričko and Pomurje in the east to Breginjnski Stol and Sečovlje salt pans in the west (Figure 3). Observations are concentrated in the areas of prolonged bird censuses, for example: Medvedce reservoir (27 observations),

Ljubljansko barje (15), Sečovlje saltpans (4), Lake Cerknica (4), Ormož lagoons (3), and also in the areas of higher birdwatching concentrations, e. g. Ljubljana basin (11) and Dravsko polje (9). Data are absent from mountainous areas in the north and northwest and forested areas in the south and southeast (Figure 3). Most of the observations were made in the lowlands. The highest altitude observation concerns an individual recorded on Mt Krvavec at 1,740 m a.s.l. (ŠERE 2011). Apart from that, Red Kite was observed above 1,000 m a.s.l. also at Breginjski Stol (BOŽIČ 2004, DENAC 2010) and at the top of Mt Pohorje above Maribor (BOŽIČ 1991).

Although the Red Kite population as a whole is in decline, the populations in Poland, Sweden (BIRDLIFE INTERNATIONAL 2015) as well as Czech Republic (KNOTT *et al.* 2009) are increasing. These migratory populations mostly migrate towards the southwest (KNOTT *et al.* 2009). Along

with a much better data-gathering tool (MIHELIČ 2016), the increases in countries to the north and northeast of Slovenia may explain the substantial increase in the number of observations. Migration periods based on Slovenian data match arrivals and departures from breeding areas (URCUN & BRIED 1998, BIRDLIFE INTERNATIONAL 2015). Since the return to breeding area mostly lasts till the end of April (BIRDLIFE INTERNATIONAL 2017), birds sighted in May are probably non-breeding individuals. The small number of winter observations is surprising since there is a tendency for birds in central Europe to overwinter, e. g. in Moravia (Czech Republic) (KNOTT *et al.* 2009). On the other hand there is a slight trend towards more winter observations of Red Kite during the winter in Slovenia. Half (3) of all observations were made in the past six years, and the last two in the past two years, but this might only be a coincidence. Higher density of

observations in certain areas could be related to the higher observation effort. On the other hand, their absence from higher altitudes and extensive forested areas could also be explained by the tendency of the species to occupy open areas at low to middle altitudes (KNOTT *et al.* 2009). Since Red Kites occur mostly in the altitude belt 0–800 m a.s.l. and rarely to 2,500 m a.s.l. (BIRDLIFE INTERNATIONAL 2015), the fact of only three sightings above 1,000 m a.s.l. in Slovenia comes as no surprise.

Abstract

The Red Kite *Milvus milvus* breeds almost exclusively in Europe, its population is in decline. In the past, it was regarded as a rare migrant in Slovenia. In the 1990s it was classified as a possible breeder, extremely rare winter guest with more observations during migration. Between 1977 and January 2017 117 records of 121 individuals were gathered. Most (113) involved single birds on migration. Exceptionally, birds were present for a longer period – a single record of a summering bird is known. Since 1980 the number of birds per year increased from 1 to 1, 1, 3 and 9 after 2009. Possible reasons are increased awareness and population increases to the north and northeast of Slovenia. Red Kites were observed throughout the year with the lowest numbers during summer and winter, which surprising, because the species is increasingly common during winter in central Europe. Migration of Red Kites in Slovenia begins in February with a peak in early April and May and between August and mid-November with a peak in early in October. The migration period coincides with arrivals and departures from breeding grounds. Red Kites have been observed all across the country, with more observations at well-watched sites. Birds were observed between sea level and 1740 m a.s.l. with only a handful of observations above 1000 m a.s.l.

Key words: Red Kite, *Milvus milvus*, phenology, migration, altitudinal distribution

Povzetek

Rjavi škarnik *Milvus milvus* gnezdi skoraj izključno v Evropi in njegova populacija upada.

V preteklosti je bil redek preletnik. V 90. letih 20. stoletja je imel status možnega gnezdilca in izredno redkega prezimovalca z več opazovanji med selitvijo. Zbrano je bilo 117 podatkov o 121 osebkih med letom 1977 in januarjem 2017. Večinoma (113) so bili opazovani posamezni osebki na selitvi. Le izjemoma so se osebki zadrževali dalj časa in zbrana sta samo dva podatka o letovanju enega osebka v dveh letih na isti lokaciji. Število opazovanj se je od leta 1980 v posameznih desetletjih dvigovalo od manj kot 1 osebek do 1, 1, 3 in 9 osebkov na leto po letu 2009. Možni razlogi za ta občutni dvig opazovanj so boljše orodje za zbiranje podatkov ter dvigi populacij severno in severovzhodno od Slovenije. Rjavi škarniki so bili opazovani v vseh mesecih leta z najnižjim številom opazovanj v poletnih in zimskih mesecih. Slednje je presenetljivo, saj vedno več osebkov prezimuje v srednji Evropi. Selitev rjavih škarnikov v Sloveniji traja med začetkom februarja z viškom začetek aprila in v maju ter med koncem avgusta in sredino novembra z viškom v začetku oktobra. Selitveno obdobje se ujema s prihodi in odhodi z gnezdišč. Rjavi škarnik je bil opazovan po večjem delu države z več opazovanji na območjih večje ornitološke pozornosti. Opažen je bil od obale do višine 1740 m n. v., z glavnino opazovanj po nižinah in le s peščico nad 1000 m n. v.

Ključne besede: rjavi škarnik, *Milvus milvus*, fenologija, selitev, višinska razširjenost
